Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

This invention relates to a matrix device for the controlled and prolonged release of at least one active agent to an ambient environment, and to a method for making such a device. More particularly, it relates to a polymeric device which has been subjected to stress for the controlled and prolonged release of at least one active agent, including a physiologically active agent, to an ambient environment, the device comprising an active agent-containing polymeric matrix wherein the polymer has been subjected to tensile stress below the yield point. Still, more particularly, it relates to such a device comprising at least one matrix as core sheet, said core sheet or sheets comprising the active agent or agents in a stressed polymeric matrix, the core sheets being sandwiched between coextensive inert polymeric films substantially impermeable to the ambient environment and to the active agent or agents, the device having one or more macroholes extending through said films and the core sheet or sheets. It also relates to such a device wherein the perimeter edges thereof, especially the perimeter edges of the core sheet or sheets are coated by an inert polymeric film substantially impermeable to the ambient environment and to the active agent or agents.

Delivery systems and devices for controlled release of drugs; i.e., controlled release and sustained or prolonged release, are well known in the art. A variety of methods have been described in the literature, including the physiological modification of absorption or excretion, modification of the solvent, chemical modification of the drug, adsorption of drug on an insoluble carrier, use of suspensions and implantation pellets (Edkins, J. Pharm. Pharmacol., 11, 54T, 66T, 1959). Other methods include mixing the drug with a carrier such as waxes, oils, fats and soluble polymers which is gradually disintegrated by the environment, e.g., body fluids, resulting in release of the drug. Much attention has been directed to the reservoir type of device; i.e., a device in which a drug is encased within a polymeric container, with or without a solvent or carrier, which allows passage of drug from the reservoir.

A further type of drug delivery device is the monolithic type in which a drug is dispersed in a polymer and from which the drug is released by degradation of the polymer and/or by passage of drug through the polymer. Included within the monolith type devices are the laminated drug dispensers.

U.S. Patent 3,926,188, issued December 16, 1975, describes three layer sandwich-type laminate drug dispensers comprising a core lamina of a crystalline drug of low water solubility dispersed in a polymer matrix interposed between two outer laminae of a drug release rate controlling polymer. A rather complex correlation between relative permeabilities, thicknesses and exposed surface areas of the laminae must be satisfied in order to achieve an approximately constant rate of drug release. The core lamina maybe a homogeneous and substantially imperforate polymeric material or it may be a microporous polymer matrix. Ethylene vinylacetate copolymer (EVA) is disclosed as representative of an imperforate polymer. It is disclosed that the release rates of said laminates are not as constant as the release rates of comparable prior art reservoir devices in which the core is not exposed to the environment.

A three layer sandwich-type laminate is also described in U.S. Patent 4,228,149, issued October 14, 1980. One such device comprises a water soluble drug dispersed in a sheet of water insoluble polymer, especially EVA, which sheet is coated (laminated) on both surfaces with a film of EVA forming a sandwich-type device. Said films may include a water soluble and/or biodegradable filler which, when the device is placed in a liquid environment, gradually decompose forming pores or channels which serve to connect the outer films with the central lamina. It is disclosed that variations in the release properties of the device can be achieved by forming a hole or holes in the sheet but not in the lamina. It is further disclosed, however, that best results are realized without such holes.

Cleave, J. Pharm. Pharmacol. 17, 698-702 (1965) presents a theoretical discussion of geometrical considerations concerning the design of uncoated tablets having a uniform rate of release. Tablets having from one to 4 holes are considered. Optimal design is concluded to reside in a two-hole tablet. A one-hole tablet is judged unable to deliver a uniform rate.

U.S. 3,851,648, issued December 3, 1974, describes devices for controlled release of a diffusible solid comprising a container having a cavity which communicates with the exterior medium and through which the contained solid is dispensed.

U.S. 4,299,613, issued November 10, 1981, describes controlled release plant nutrient dispensers comprising an admixture of a plant nutrient, a porosigen and a polymer matrix.

Controlled delivery systems consisting of a polymer impermeable to a fluid environment and to active agent contained within said polymer, said polymer in laminar arrangement with a polymer that forms a microporous structure in a fluid environment are described in U.S. Patent 4,217,898, issued August 19, 1980.

Medicament containing tablets comprising a medicated portion soluble in gastrointestinal fluids, which portion is surrounded by an inert portion said inert portion having one or more holes extending through one

face of said inert portion into said medicated portion to permit passage of said medicated portion into the gastrointestinal fluids when such a device is in use, are disclosed in U.S. 3,146,149.

Slow-release veterinary preparations comprising a veterinary medicament contained in a matrix which in turn is enclosed in a plastic envelope sealed at its edges and provided with a number of randomly placed small holes to render it permeable to rumen fluids, thus permitting access of said fluids to the medicament contained within the matrix within the envelope, are made known in European Patent Application 21,758, published January 7, 1981.

Rhine et al., in "Controlled Release of Reactive Materials", R. Baker, Ed., Academic Press, p. 177, 1980 present a discussion of the effect of matrix geometry on the rate of release of a drug from a matrix device comprising an inwardly releasing hemisphere. They demonstrate that such a device can, after a short burst of drug, achieve essentially zero order release rate for the duration of release. For a device of such geometry, the outer diameter should be greater than three times the inner diameter. Also, Rhine et al., A. I. Ch. E. Symp. Ser. 77, 10-20 (1981), discuss the release characteristics of an inwardly releasing sectioned cylinder.

International Patent Application WO 86/00538 discloses temperature and/or polar fluid - sensitive devices comprising mechanically strained semi-crystalline hydrophilic polymers, the strained polymers exhibiting deformation "memory" which is activated by heat or a solvent.

U.S. Patent 4,601,893, issued July 22, 1986, describes unstressed laminate devices of the type disclosed and claimed herein. For a given concentration of active agent the stressed laminates of this invention exhibit an increased release rate of active agent over the release rate of unstressed laminates of said patent. All the matrix systems (described in the prior art) having a fixed concentration of the active ingredient have an "inherent" release rate per unit area of releasing surface which can not be altered. The present invention discloses a method to controllably alter the drug release rate per unit area of drug release surface after the matrix is prepared, without changing the composition or design of the matrix system. Precise control of drug release rate from a matrix system is usually difficult. The drug release rate is extremely sensitive to small variations in composition. The present invention offers a technique to apply positive corrections to the drug release rate from a matrix system after its manufacture.

This invention relates to a matrix device for the controlled release of at least one active agent, including a physiologically active agent, to an ambient environment, especially to an aqueous liquid-containing environment, over a prolonged period of time. More particularly it relates to such devices comprising an active agent, or agents, containing polymer which has been subjected to tensile stress below the yield point, and which are useful for the controlled release of active agent or agents to an ambient environment, especially when the active agent is a physiologically active substance, and especially when the environment is the rumeno-reticular sac of a ruminant animal, the active agent being released over a prolonged period of time at a controlled physiologically acceptable rate. Preferred devices comprise a laminate which has been subjected to stress comprising at least one matrix as core sheet, said core sheet or sheets comprising the active agent or agents in a stressed polymeric matrix, the core sheet or sheets being interposed or sandwiched between coextensive inert polymeric films substantially impermeable to the active agent or agents and to the environment to which the device is exposed. One or more macroporations extend through the coextensive films and through the core sheet or sheets. The perforations give rise to development of inwardly releasing cylinders when the devices are in use.

Those skilled in the art will recognize that this invention can embody various types of matrices including agent dissolved in polymer (dissolved matrix), agent dispersed in a polymer at a concentration which exceeds its saturation solubility in the core polymer (dispersed matrix) and agent dispersed in a polymer at a concentration sufficient to produce continuous solvent filled channels within the polymer matrix upon depletion of the drug (porous matrix). Each of these types are useful embodiments of this invention which, by appropriate choice of agent, polymer and device design, including hole pattern, and exposure to tensile stress below the yield point, achieve a given overall release pattern as a function of time.

The devices of this invention provide a simple and practical, essentially zero order release device, by reason of their having at least one interior-releasing cylindrical surface wherein the entire surface of the cylinder participates in the release process.

They offer advantages over the controlled release devices previously available, especially over the matrix devices, including monolithic and laminate systems, of the art. Additionally, the present invention offers a novel technique to independently control the drug release rate from a matrix system without changing its composition or design. One advantage is the relative ease of manufacture of the devices of this invention. Other advantages are the nearly constant (zero order) rate of drug release over a prolonged period, and their ability to achieve a greater release of active agent in a given time period than are non-stressed devices of similar construction. Alternatively, the devices of this invention require a lesser charge

of active agent to achieve a given release rate than do non-stressed devices of similar construction. These advantages, along with others which will become apparent to one skilled in the art, render the devices of this invention practical, non-reservoir type devices which are especially valuable for field use in ruminants.

The laminates of this invention can comprise a three layer (sandwich-type) laminate comprising a core sheet containing one or more active agents, said core sheet sandwiched between two coextensive inert polymeric films which are substantially impermeable to the use environment and to said agent. The edges of the laminate may be uncoated or coated. The laminates can also comprise two or more active agent-containing core sheets, each core sheet being sandwiched between coextensive inert and impermeable polymeric films so as to provide alternating layers of film and core sheet. The edges of the laminate are uncoated in one embodiment of this invention. Alternatively, a further embodiment comprises laminates in which the edges are coated; i.e., there are no exposed edge surfaces.

The laminates of this invention, whether they comprise one or more than one core sheet and whether the edges thereof are exposed or unexposed are characterized by said core sheet comprising at least one active agent, including dispersions and solutions of active agent, homogeneously dispersed therein when a constant release rate, as opposed to a pulsed release rate, is desired; and at least one macrohole extending through said core sheet and through the films coextensive therewith, the size, number and arrangement of said macroperforations in relation to the thickness of said core sheet being selected to expose sufficient interior edge area of said sheet to the use environment as to afford the desired release rate.

Devices of this invention which are comprised of two or more core sheets are especially valuable for controlled release of two or more active agents to an ambient environment. The fact that the properties of the individual active agents (e.g. solubility, vaporizability, potency, etc.) will differ is compensated for by incorporating, for example, into the core sheet containing the more potent active agent a suitable diluent or filler (e.g. porosigen) in sufficient amount to moderate the release rate of said agent. Of course, the two or more active agents must be compatible with one another in the use environment.

In devices of this invention comprising two or more active agent-containing core sheets, said sheets need not be separated from each other by impermeable polymeric films but can be in contact with each other. While such construction tends to reduce the overall thickness of a given device, the favored devices of this invention employ coextensive inert, impermeable polymeric films between two or more core sheets. This latter construction simplifies calculation of in vitro release rates since the active agent is exposed to the ambient environment only from the direction of the advancing solvent boundary at the surface of the cylinder.

A necessary requirement as regards the coextensive polymeric films is that they be substantially impermeable to the active agent in the core sheet. However, the core sheet need not be impermeable to the active agent as is the situation wherein the active agent is dissolved in the core sheet. However, for many uses of the devices of this invention the core sheet can comprise a polymeric material which is substantially impermeable to the active agent.

The film and core sheets can be, but need not be, made of the same polymeric material. Suitable polymeric materials are those which are substantially inert to the ambient environment; i.e., do not react chemically with any active agent which might be dispersed or dissolved within them, or with their environment, and, as regards said film, are substantially impermeable to the ambient environment. Additionally, for certain configurations of the devices of this invention, especially those having variable geometry; i.e., have one configuration when not in use and assume another configuration in the use environment, flexibility and resiliency are desirable and advantageous properties for said polymeric materials. Representative polymers fulfilling these criteria are ethylene vinylacetate copolymers which may be partially or completely hydrolyzed, poly(ethylene), poly(propylene), poly(vinyl chloride) vinylidene chloride-acrylonitrile polymers; copolymers of vinyl chloride with vinyl acetate, styrene, vinylidene chloride, dialkyl fumarate, acrylonitrile; polyacrylonitrile, poly(butylmethacrylate), poly(vinylidene chloride), polybutadiene, polyether urethane, cross-linked poly(vinylpyrrolidone), chlorinated poly(ethylene); polyacrylamide, and crosslinked partially hydrolyzed polyvinylacetate, hydroxyethyl acrylate, diethylene glycol monoacrylate, diethylene glycol monomethacrylate, 2-hydroxypropyl acrylate, 2-hydroxypropyl methacrylate, 3-hydroxypropyl acrylate, 3-hydroxypropyl methacrylate, vinylpyrrolidone, acrylamide, methacrylamide and N-propylacrylamide, silicone rubbers, especially medical grade poly(dimethylsiloxanes), poly(carbonates), silicone-poly(carbonate)copolymers; biodegradable polymers such as poly(lactic)acid, poly(glycolic)acid, poly(caprolactone) and copolymers thereof; and others known to those skilled in the art and which meet the above criteria. Ethylene vinylacetate copolymers (EVA) are preferred materials. Especially preferred are EVA containing from 10% to 60% vinyl acetate.

The polymer used for the core sheets can be a microporous polymer that is preformed and subsequently charged with the desired substance or substances. Alternatively, the core sheet is made from

an imperforate polymer which, when charged with the desired substance or substances forms a microporous polymer when a device incorporating said core sheet is placed in the use environment. When the core sheet is to comprise a microporous polymer, the choice of a preformed microporous polymer or one formed in situ is determined in large part upon the amount of and distribution of the active agent present in the core sheet. Sufficient agent must be present for in situ formation of a microporous core sheet as will give rise to continuous formation of interconnected paths, channels and micropores with development of the desired microporosity when the device is in use.

A further method for in situ formation of a microporous core sheet comprises the use of a suitable porosity enhancing agent, a porosigen, in admixture with the desired active agent to be released. Said porosigens can be biodegradable, volatile or water soluble. They must be removable under the conditions of use of the devices of this invention and, of course, non-toxic under said use. Said porosigens have been referred to in the literature as modifying agents (U.S. 3,538,214) and as fillers (U.S. 4,228,149). They may also be referred to as diluents. The term "porosigen" as used herein is intended to embrace the aforementioned terms. The use of a porosigen is advantageous in instances wherein the amount of active agent contained within the core sheet is insufficient to give rise to contact between individual particles of said agent and thus prevents formation of interconnected pathways and channels (continuous micropores) when a device of this invention is in use.

The choice of porosigen depends upon the active agent in the core sheet and the use environment. Said porosigen must be compatible; i.e., not react with the agent or the environment to produce a reaction product having undesirable properties. It must be removable under the conditions of use and non-toxic or harmful. Favored porosigens for use in devices scheduled for use in an aqueous environment are starch, lactose, inorganic salts such as carbonates, bicarbonates, sulfates, nitrates, phosphates of the alkali metal, alkaline earth metal, ammonium, and buffering agents. Other porosigens are disclosed in the art cited herein and are incorporated herein by reference. The expression active agent as used herein applies broadly to include any substance, solid, liquid or gaseous, which can be released to a use environment to produce a beneficial effect. This includes anti-oxidants, air purifiers, pesticides, fungicides, insecticides, germicides, herbicides, preservatives, rodenticides, disinfectants, sterilization agents, foods, food supplements, drugs, nutrients, vitamins, fertility promoters, fertility inhibitors, growth promotants, trace minerals, perfumes, pheromones, chemicals released to control the rate of various reactions, and other substances that benefit the environment of use. The active agent can be organic or inorganic but must be sufficiently soluble in the release environment when said environment is a liquid environment, or sufficiently volatile when said environment is a gaseous environment, that devices of practical size can release said agent in sufficient quantity to produce the desired effect.

The term "drug" includes any physiologically or pharmacologically active agent that produces a beneficial effect in the release environment, including biological environment. The term "biological environment" includes mammals, primates, humans, animals (domestic, household, zoo, sport and laboratory), birds, reptiles and fish. Representative of drugs are those substances which exhibit antiparasitic, anti-biotic, antimicrobial, anti-inflammatory, analgesic, antiparkinson, anti-spasmodic, anthelmintic, anti-neoplastic diuretic, hypoglycemic, anesthetic, hormonal, estrogenic, progestational steroids, prostaglandins, sedatives, hypnotics, narcotics, tranquilizers, anti-convulsants, muscle relaxants, cardiovascular agents and electrolytic behavior. The required doses for such drugs are known in the literature.

The macroperforations in the devices of this invention, together with the impermeable coating on the device surface, provide interior edges for release of active agent when the devices are placed in the use environment. These macroperforations are preferably cylindrical in shape and from 0.5 - 10 mm in diameter, but could assume other geometric forms such as ovals, triangles, squares, pentagons, hexagons, etc.

For a given core sheet, the dimensions of macroperforations other than the cylindrical; i.e., those wherein the surface openings are circular, should be such that the perimeter of the macroperforation at the surface of the opening approximate as closely as possible the circumference of circular openings of from 0.5 - 10 mm diameter. Circular macroperforations, actually cylinders when considering the overall shape through the core sheet, most nearly attain zero order release. The closer to a circle the macroperforation is, the closer it approximates zero order release.

The rate of active agent release from the macroperforations is dependent upon a number of factors (see above equations) including the effective surface area at the receding agent boundary, the length of the channel from the receding agent boundary to the interior edge of the macroperforation, the initial active agent load in the device, the diffusion coefficient for said agent in the use environment and/or core sheet, the solubility of the agent in the use environment and/or core sheet, and the number and shape of the macroperforations. Over time, all of the above factors except the first two should be constant. Thus, the

variations in the release rate over time will depend upon the relative changes in these two factors. With most other devices wherein active agent release occurs from a surface which is either planar or convex, the release rate will always dramatically decrease over time due to the increase in the diffusional distance and the decrease in the area at the receding active agent boundary. In the present invention, the macroperforations are designed such that active agent release occurs from a concave surface so that the surface area at the receding drug boundary increases over time. This increasing surface area leads to an increasing release rate which partially offsets the effects due to increasing diffusional distances. Overall release is nearly zero order following an initial burst of the agent. The precise variation depends upon the size and shape of the macroperforations. The smaller the diameter of the macroperforations, and the more circular their shape, the more linear the release rate over time.

The devices of this invention can be used to release a given active agent at essentially zero order rate at one level for a certain time and then to release it at a greater or lesser level, again at essentially zero order rate, for a further period of time. A convenient way of accomplishing such a release pattern comprises incorporating the active agent and porosigen, or porosigen plus active agent, in concentric patterns within the core sheet. Proper placement of macroperforations then allows one to achieve a pulsed release of active agent.

Other methods can, of course, be used to achieve a pulsed release of active agent. In addition to the use of a variable concentration of active agent within the core sheet, as described above, variable thickness of the layer of active agent within the core sheet is a practical way of realizing pulsed release. Further, the core sheet can, for example, have grooves of varying width and depth, said grooves being filled with active agent.

Devices of this invention having active agent-containing core sheets constructed as described above, are useful for essentially zero order release of more than one active agent as those skilled in the art will recognize.

Still further, when microporous EVA is used for the core sheet, advantage can be taken of the fact that high temperature reduces its tortuosity. Thus, certain portions of an active agent-containing microporous EVA core sheet can be heated so as to reduce the tortuosity of the micropores in said portions resulting in an increase in the rate of release of active agent therefrom. Proper placement of the number and size of the macroperforations affords a change in release rate of active agent from a device having such a core sheet.

Asymmetrically placed macroperforations can also be used in devices of this invention. They are especially useful in situations wherein a biphasic release rate of active agent is desired. In such devices an initial high release rate followed by a reduced but constant zero order release rate occurs and is followed by a second reduced release rate at near constant level.

Favored devices of this invention have macroperforations symmetrically or substantially symmetrically, rather than randomly, placed through both outer lamina and through the core lamina. In such embodiments of this invention, the macroperforations, preferably circular, penetrate all laminae through the smallest dimension thereof. The macroperforations can vary in diameter from 0.5 to 10 mm. Preferred devices have macroperforations of from 2 to 5 mm diameter since, when using a water soluble active agent, for example, a salt of morantel, as the agent to be released over a prolonged period of time, said diameters most closely afford essentially zero order release rate over an extended time.

For a given type device (three-layer laminate having exposed or unexposed edges) of this invention, the rate of release of a given active agent is a function of the number and size, e.g., diameter, of the macroperforations as well as of their design, i.e., symmetrical versus non-symmetrical.

For a given size device and a given water soluble agent, the release rate increases with increase in diameter and/or number of the macroperforations. The number and diameter of the macroperforations required in a given device depend upon the agent, the rate and duration of release desired and are determined by experiment or can be calculated by means of equations known to those skilled in the art.

The invention also provides methodology for making devices of this invention. In the case of devices comprising at least one core sheet, said core sheet comprising a substance dispersed therein, said core sheet being sandwiched between coextensive films of inert polymer, a convenient method comprises blending said substance into the softened, pre-formed polymer of said core sheet by known methods until a homogeneous mass is obtained. Said mass is then rolled into sheets of the desired thickness and of approximate width of the device desired, then sandwiched between said films of inert polymer and laminated or bonded thereto, desirably by applying pressure and heat sufficient to achieve bonding but insufficient to destroy said substance and said core sheet and film. The preferred method is by extrusion coating of the active agent containing matrix according to known procedures especially that described in "Extrusion Coating Manual" by UST, 99 Park Ave., N.Y., N.Y. 10016.

The devices thus prepared are then subjected to tensile stress which does not exceed the yield point of

the polymer matrix or polymer matrices. This operation can, of course, be carried out in a number of ways as those skilled in the art will recognize. A convenient method is to apply a constant rate of strain, for example, by means of an Instron machine (Instron Model #1115, Instron Corporation, 100 Royal Street, Canton, MA 02021). The stress is normally applied in only one direction, usually along the length. It can, however, be applied along the width or the bias (diagonal), or along any of said directions in step-wise or concurrent fashion. The maximum allowable tensile stress, of course, varies from polymer matrix to polymer matrix. It is, however, readily determined as, for example, as described by F. Rodriguez, "Principles of Polymer Systems", McGraw Hill (1976). In general, a constant strain rate is applied to the device. The rate and range of strain are desirably held below levels which give rise to necking or stress whitening. They are preferably applied at levels at which 95% to 100% of the imposed strain is recoverable. Devices thus treated are identical to or almost identical to non-stressed devices in appearance. A strain rate of from about 1 cm/minute to 10 cm/minute meets the above criteria for most polymer matrices enumerated herein. For the ethylene vinyl acetate copolymer matrices exemplified herein a strain range of from about 7% to 35% is satisfactory. The strain range refers to the extent the original polymer is stretched (in terms of percent increase) in a given dimension. The stressed devices afford a greater release rate than do unstressed devices. The release rate increases with increase in strain level. The laminate is then cut to the desired dimensions. Before or after cutting of the laminate, perforations of the desired size and arrangement are made therein by known techniques. (Porosigens, if used, are blended into the core sheet along with the desired substance).

Alternatively, the active agent-containing core sheet is subjected to tensile stress prior to being sandwiched between the films of inert polymer; i.e., prior to laminate formation. This procedure, which applies stress only to the active-agent containing core sheet, eliminates the possibility of the coextensive sheets separating from the core sheet during the application of stress to the laminate. The rate of release of active agent from a device made in this manner is the same as that of a device produced by the first described procedure.

The herein described methodology is also applicable to laminated systems which lack macroperforations and in which release is achieved only via uncoated areas, e.g., edges; or in which the coextensive sheets covering the core sheet are permeable to the active agent and the environment.

While the favored method of bonding the core sheet and said coextensive films of inert polymer is by means of pressure and heat, it may be necessary, as when the active agent is volatile or heat sensitive, or at least more convenient, in certain instances to use a binder. The particular technique used depends upon the polymers used for the core sheet and the coextensive films and the nature of the substance in the core sheet. The binder used must, of course, be inert and compatible with the polymers used in the device, the substance within the core sheet and the use environment. Suitable binders are disclosed in Encyclopedia of Polymer Science and Technology, John Wiley & Sons, 8, 1968.

When the active agent is a solid substance which vaporizes over a period of time, e.g., certain insecticides, the use of heat in the bonding process is, of course, detrimental. In such instances, bonding is achieved by use of a binder. Similar technique is used when the active agent is a liquid.

When the active agent is a liquid, it is preferred to use a preformed microporous polymer for the core sheet. Said sheet is precharged with the liquid active agent in a known manner as, for example, by immersing the microporous in said liquid active agent or in a solution of said liquid active agent of known concentration followed, in the second instance, by evaporation of the solvent to leave the micropores charged with liquid active agent.

The controlled release devices of this invention can be used for a variety of purposes and situations wherein prolonged controlled release of active agents, including drugs, is desirable. They can be used for administering and for providing said agents at sites near to or remote from the point of application of the device. They can be positioned by appropriate means in suitable locations within the animal body where they are in contact with body fluids, e.g., the stomach of farm animals, especially the rumeno-reticular sac of ruminants; or on the animal body, e.g., flea collars, ear tags. Still other uses for the controlled release systems and devices of this invention occur in agriculture for administration of fertilizers, herbicides, rodenticides, pheromones, sex sterilants and pesticides; in pisciculture including aquariums and fish ponds; in drainage ditches, canals and tanks as for controlled release of algicides, biocides, disinfectants, plant growth inhibitors and promoters; and in water supplies especially for animals and poultry in need of drugs for therapeutic or prophylactic treatment.

The amount of active agent dispersed in the core sheet can vary over wide limits depending upon a variety of factors such as the amount of said agent to be delivered to an ambient environment, the time over which said agent is to be delivered, the presence or absence of a porosigen, the number and size of the macroperforations in the device, the nature of said agent and said environment and, in the case of liquid

environments, the solubility of said agent in said environment.

The amount of a given agent which must be used in a device of this invention to achieve a given release rate, or determination of the release rate of a given device of this invention, is determined by in vitro tests as those skilled in the art will recognize. In general, such tests involve placing the device in question
 5 in an environment approximating the ambient environment of ultimate use intended for said device, and measuring by appropriate methodology known to those skilled in the art the amount of said agent released to said environment over a given period of time and/or by determining the amount of said agent remaining in the device after a given period of time.

In the case of a highly preferred device of this invention intended for delivery of an anthelmintic,
 10 especially morantel or a salt thereof, to the rumenoreticular sac of a rumen, the amount of morantel (active agent) homogeneously dispersed throughout the core sheet can range from 10% to 75% by weight of said sheet. When the core sheet comprises morantel or a salt thereof dispersed in EVA, amounts greater than 75% by weight of the core sheet tend to reduce the flexibility of said sheet.

The devices of this invention can be of fixed or variable geometry. Fixed geometry devices; i.e. those
 15 which do not change their configuration in the use environment, are of value as, for example, implants, suppositories, ocular inserts, transdermal release reservoirs, vaginal inserts, ear tags for animals, dog collars, releasers of insecticides, pheromones, larvicides, molluscicides, water purification chemicals, biocides, perfumes and antibiotics; and other uses as mentioned above.

Variable geometry devices; i.e., those which undergo a change in configuration when placed in the
 20 intended use environment, are of particular value for use in environmental situations in which a controlled release device is subject to expulsion or removal before it has completed its intended task. Such situations occur, for example, in the rumen-reticular sac of ruminant animals such as cattle and sheep. Orally administered devices must not exceed certain size and configuration for successful and convenient administration to a ruminant. However, to avoid their regurgitation by the ruminant they must be properly
 25 weighted or be of such a configuration as to prevent or at least minimize their regurgitation. Obviously, the latter property requires a device which permits convenient per os administration but which, in the rumen environment, undergoes a change in configuration thus preventing regurgitation.

The highly favored devices of this invention, especially those intended for oral administration of active agents, such as anthelmintics and growth promotants to ruminants, are of variable geometry. The preferred
 30 devices are the three layer (sandwich) stressed laminates comprising a single core sheet and two outer films, said devices having variable geometry. Among said devices particular preference is given to those having exposed core sheet edges. In the open configuration in the use environment, the most preferred devices are rectangular in shape so as to permit retention within the rumen. Prior to administration they are rolled into constrained cylindrical shape for easy oral administration to a ruminant. For this reason the
 35 flexibility and especially the resiliency of the core sheet are important and must not be destroyed or reduced to a level at which they fail to restore the cylinder to a substantially rectangular shape, or at least to unroll the cylinder sufficiently so as to permit retention of the device in the rumen-reticular sac (rumen) of a ruminant.

In the case of a highly preferred device of this invention intended for delivery of an anthelmintic,
 40 especially morantel or an acid salt thereof, e.g. citrate or tartrate to the rumen-reticular sac of a ruminant, the amount of morantel, calculated as acid salt, in the core sheet is generally from 10% to 75% by weight of said sheet. The morantel or salt thereof is finely divided prior to being dispersed in the core sheet to enable maximum dispersion and maximum homogeneity of drug therein. The above mentioned amounts of morantel insure that contact between individual particles is maintained so that when the device is placed in
 45 operation in a liquid environment, e.g. rumen of a ruminant, diffusion of morantel in said environment forms interconnected paths affording continuous release of said morantel.

For administration to a ruminant the devices are rolled so as to provide cylinders the height of which equals the shorter dimension; i.e., the width, of the device in the open configuration. The cylinders are, for ease of administration, constrained in said configuration by suitable constraining means, e.g. biodegradable
 50 string, tape or glue, water soluble adhesive, paper or gelatin capsule.

The dimensions of the preferred devices of this invention which are intended for per os administration of morantel or other substances to ruminants are not critical. As those skilled in the art will recognize the dimensions will depend in part upon the particular species of ruminant being treated.

In general, for bovines, the overall practical dimensions of the devices prior to their being rolled and
 55 constrained into cylinders for oral administration to said bovines are on the order of 7-15 cm long, 4-10 cm wide and overall thickness of 2-4 mm. Devices of these dimensions allow for convenient administration to bovines and appropriate loading of desired agent for effective treatment of said bovines.

The core sheet is suitably from 1.0 to 2.0 mm thick and the outer films from 0.1 to 0.75 mm thick. In

general, the drug-containing core sheet is thicker than the total thickness of the outer films which, for simplicity of construction, are of equal thickness.

One of the major advantages of the device design described herein is that the thickness of these coatings need not be carefully controlled. In other laminated devices with rate limiting barriers such as those described in prior art, the coatings are the rate limiting barriers and therefore the thickness must be precisely controlled.

The devices when rolled and constrained into cylindrical form are, for convenient and practical reasons, from 2.0 to 3.0 cm in diameter for use in bovines.

For use in sheep, the herein described devices are, of course, smaller in size than are those for use in bovines. Dimensions ranging from 5-10 cm long, 3-8 cm wide and 1-3 mm thickness are suitable for sheep. Core sheet thickness can range from 0.4 to 2.0 mm and the outer films from 0.1 to 0.75 mm thickness. The diameter of the constrained forms is from about 0.8 to 1.5 cm in diameter.

The criterion for suitable active agents (drugs or chemicals) for use in the devices of this invention is that they be sufficiently soluble or volatile in the use environment to achieve a rate of release of said agent in said environment which will produce the desired result. For this reason, active agents which are acids or bases are often used in the form of a salt thereof. For the purpose of this invention a water soluble drug is one having a water solubility of 0.01% w/v or greater within the use environment.

Representative of the drugs which can be used in the devices described herein are the following: anthelmintics, including salts thereof, of morantel, pyrantel, oxantel, piperazine, diethylcarbamazine, levamisole, tetramisole, ivermectin and hygromycin B; antibacterials, including salts thereof, of tetracyclines, such as 5-oxytetracycline, tetracycline, chlorotetracycline, doxycycline and Mannich bases thereof; beta-lactams such as sodium ampicillin, pivampicillin hydrochloride, penicillin G, cephaloridine, sodium salts of cefazolin, cefoxitin, cephalixin and other beta-lactams of established clinical utility; aminoglycosides such as neomycin, streptomycin, apramycin, macrolides such as erythromycin, oleandomycin and tylosin; antibacterial growth promotants such as bacitracin as its zinc or methylene disalicylic acid derivative, salts of avoparicin, polymyxin, lincomycin, bambarmycin and efrotomycin; performance enhancing agents including estradiol, synovex, bovine growth hormone, diethylstilbestrol, zeranol; antiparasitic agents such as milbemycins and amprolium; essential minerals such as salts of magnesium, copper and cobalt; and vitamins such as thiamine hydrochloride; sulfa drugs such as sulfamethazine, molluscicides such as N-tritylmorpholine; and bloat prevention agents such as alcohol ethoxylates and poly(oxyethylene)-poly(oxypropylene)-poly(oxyethylene)-polymers, e.g. poloxalene; ionophore performance-enhancing agents such as salinomycin, monensin, narasin and lasalacid; larvicides such as 2-chloro-1-(2,4,5-trichlorophenyl)-vinylidimethylphosphate; insecticides such as phosphorothioic acid O[4-[(dimethylamino)sulfonyl]phenyl]-O,O-dimethyl ester, isopropyl 11-methoxy-3,7,11-trimethyldodeca-trans-2-trans-4-dienoate and phosphoric acid 2,2-dichloroethenyl dimethyl ester; flukicides such as 2,3,5-trichloro-N-(3,5-dichloro-2-hydroxyphenyl)-6-hydroxybenzamide, 4-hydroxy-3-iodo-5-nitrobenzonitrile and N-[3-chloro-4-(4-chlorophenoxy)phenyl]-2-hydroxy-3,5-diiodobenzamide; and pheromones such as 2-decyl-3-(5-methylhexyl)oxirane and (Z,E)-7,11-hexadecadien-L-ol-acetate for the control of gypsy moth and pink ballworm, respectively.

The devices of this invention are especially valuable for the control (therapeutic and prophylactic) of helminth infections in ruminants, cattle in particular. Protection of range animals becomes relatively convenient. In temperate climates, the low, early spring population of pasture larvae, the residue of the previous season's contamination, is multiplied by cycling through animals grazing thereon to produce, in the summer, a sharp increase in pasture infectivity. This condition gives rise, during the summer grazing season, to clinical parasitism and performance depression of animals grazing on said pasture.

The continuous and controlled release of anthelmintic agent; e.g. morantel, in the rumeno-reticular sac of grazing animals early in the season when pasture contamination is low, suppresses helminth development, deposition of eggs and subsequent larval contamination of pasture and thus breaks the above-mentioned cycle and keeps the pasture and animal worm burden at a low level. Parasitic infections of ruminants grazing on the same pasture land during the summer season is thus minimized. This "indirect" method of helminth control is especially attractive and valuable for calves since they are highly susceptible to helminths when first placed on pasture. Consistent use of the devices reduces the reservoir of infective helminth forms at a given location and at least minimizes the seasonal increase in pasture larvae which causes parasitic gastroenteritis and performance depression in grazing animals later in the season.

For "indirect control" of helminths the devices of this invention are administered to ruminants at a time in the epidemiological cycle of said helminths when pasture contamination by infective larval stages of said helminths, is declining to a minimum level. In temperate zones, this time corresponds to spring turn out; that is, the first placing of the calves out to pasture. For maximum efficiency, the device is administered to the calves within seven days of turning out. In non-temperate zones of the world, e.g. semi-tropical and

tropical areas, the period of lowest pasture infectivity normally occurs prior to the rainy season. Administration of the device to ruminants in such areas is desirably carried out within two to fourteen days before the start of the rainy season.

The herein-described devices also eliminate established helminth infections from ruminants and prevent establishment of worm infections during the period of heavy challenge (summer/autumn in temperate zones). This mode of use is called "direct control". Helminth control in the non-temperate zones can also be achieved by the "direct control" method. The direct method of control protects ruminants only during the period of release of the anthelmintic agent. The indirect method of helminth control protects ruminants grazing on a given pasture for the entire season because it achieves an overall significant reduction in pasture contamination. As noted, the devices described herein provide continuous release, at a controlled rate, of drugs including anthelmintics. Particularly useful for such purposes are water-soluble salts of (E)-1',4,5,6-tetrahydro-1-methyl-2-[2-(3-methyl-2-thienyl)ethenyl]pyrimidine (morantel), (E)-1',4,5,6-tetrahydro-1-methyl-2-[2-(2-thienyl)ethenyl]pyrimidine (pyrantel) and (\pm)-2,3,5,6-tetrahydro-6-phenylimidazo[2,1-b]thiazole (tetramisole) and levamisole, the L-(-)-form thereof. Representative of preferred water-soluble salts of pyrantel and morantel are the tartrate and citrate salts; and of tetramisole and levamisole, the hydrochloride salts.

The devices of this invention are orally administered to animals by, for example, a balling gun. For use in calves, the desirable average release rate of morantel (calculated as base) is of the order of 60-200 mg (of morantel base) per day for a period of about 90 days, which covers the normal maximum survival time of the spring population of larvae. Longer release periods of from 60-180 days are desirable in the direct control mode of use since the period of exposure to heavy pasture contamination is normally prolonged. Release rates of about 60-200 mg (calculated as morantel base) per day effectively control helminth infections over such release periods. For dosing larger animals, more than one device can be administered. For indirect control of helminths using salts of pyrantel or levamisole, the desirable average release rates of each (calculated as free base) are on the order of 100-400 mg, and 100-500 mg per day, respectively for about a 90 day period. For direct control, release rates of about 100-500 mg (as free base) of pyrantel and of about 100-400 mg (as free base) of levamisole per day effectively control helminth infections over the 60-180 day period of heaviest challenge.

Continuous, low-level administration of morantel by use of the herein described devices for helminth control is effective in preventing lung worm infections in said animals during the period of drug release. Further, while cattle or sheep grazing on contaminated pasture are subject to immediate reinfection by intestinal nematodes after conventional therapeutic dosing, animals receiving the devices of this invention are essentially freed of established infection and protected from reinfection over a period of 60 days or longer.

The use of the devices for control of pasture contamination, i.e. the indirect control method, is a practical and effective method of helminth control which protects ruminants, and in particular grazing ruminants, treated via this mode for the entire grazing season. The increase in daily weight gain over untreated controls over the grazing season is substantially greater than that obtained after conventional therapy.

The rate of release of drug, or other chemical, from the controlled release devices of this invention can readily be determined by those skilled in the art, for example, by transmission methods, or by sorption-desorption methods. A technique which can conveniently be used comprises placing a given device in a rapidly stirred solvent bath, the composition of which simulates the aqueous liquid containing environment in which the device is to be used. The temperature of each solution is maintained at a value approximating the average temperature of the environment in which said device will be used. Samples are withdrawn at predetermined intervals from the solvent bath and analyzed for drug concentration.

In vivo release of morantel citrate or tartrate from devices according to this invention is determined by administering the devices to, for example, normal steers or steers with rumen fistula and, after a certain period of time such as 30, 60, 90 or 120 days, removing the devices via the fistula or sacrificing the animals and recovering the devices to determine the residual morantel citrate or tartrate within the device. Tests of this sort have shown that the rate of release of morantel citrate or tartrate in vivo is approximately 1.0 to 1.5 times that of the in vitro release rate.

EXAMPLE 1

Devices of this invention comprising a laminated device having morantel tartrate as the active agent and laminae of EVA was prepared as follows.

A sheet containing 50% morantel tartrate and 50% EVA (Type MU-760 having 19% vinyl acetate

content, available from U.S.I. Chemicals Co., 99 Park Ave., New York, N.Y. 10016) was prepared by dry blending 15 kg morantel tartrate and 15 kg EVA in a 55 gallon (208 liter) fiber drum on a drum roller for 30 minutes. It was then milled at high speed to produce a mixture which passed through a 0.033 inch (0.0838 cm) screen and then drum rolled for another 30 minutes.

5 The resulting mixture was extruded on a 1 1/4 inch (3.75 cm) single screw extruder with three heating zones and a 24:1 1:d general purpose screw. The three heating zones of the extruder barrel were set to 88°, 102° and 107°C. and the screw was operated at 79 rpm. The die was a 6 inch (15.24 cm) adjustable sheet die opened to 0.110 inch (0.279 cm) and with temperature set to 88°C. The extruded sheet was passed through a three roll take-up with chilled rolls and collected.

10 The extruded sheet was then coated with EVA UE-633 (available from U.S.I.) by extrusion coating; a thickness of 0.005" (0.127 mm) being applied first to one side and then to the other side by standard methodology.

5.08 x 25.4 cm. pieces of coated sheet were then subjected to various tensile strain levels at a strain rate of 5 cm/minute using a standard Instron machine. A total of 33 holes (2.7 mm. diameter) were punched 15 into each device. It was noted that 95% to 100% of the imposed strain was recoverable.

EXAMPLE 2

The in vitro release rates of the stressed devices of Example 1 and of an unstressed device of the 20 same dimensions and composition were determined by the following procedure:

The test or control device was placed into a two-liter conical flask which was protected from light because of the photosensitivity of morantel tartrate, 1700 ml of distilled water added, and the temperature of the flask and contents maintained at 40°C. The flask containing the device was shaken at about 85 excursions of about 3 inches (7.62 cm) per minute and 5 ml samples were withdrawn periodically. The 25 volume of the withdrawn sample was replaced with an equivalent volume of distilled water and shaking of the flask continued. The concentration of morantel in the samples was determined spectrophotometrically by measuring the absorbance of the sample at 318 nm.

The rate of morantel (base) released is tabulated below:

30	% Strain	Release Rate (mc/day)	Correlation Coefficient	% Increase In Release Rate Over Control
	0 (control)	39	0.989	----
35	7.3	43	0.994	10.3
	15.0	47	0.980	20.5
	20.0	51	0.990	30.8
40				

Claims

- 45 1. A matrix device for controlled release of an active agent to an ambient environment comprising an active agent-containing polymer matrix which polymer has been subjected to tensile stress below the yield point.
2. A device according to claim 1 wherein said active agent-containing polymer matrix is present as a core 50 sheet sandwiched between coextensive polymeric films which are impermeable to said environment and to said agent; said device having at least one macroperforation extending through said coextensive polymeric films and said core sheet.
3. The device of claim 2 wherein said macroperforations are symmetrically distributed over the face of 55 said device and said core sheet comprises a homogenous mixture of active agent in the polymer matrix.
4. The device of claim 3 wherein said macroperforations are circular to afford interior edges of cylindrical

configuration for exposure of said agent to said environment.

5. The device of claim 4 wherein said macroperforations are from 0.5 to 10 mm in diameter.
- 5 6. The device of claim 2 wherein the perimeter edge of said core sheet is coated by a film impermeable to said environment and to said agent.
7. The device of claim 2 wherein said agent is dispersed in said core sheet.
- 10 8. The device of claim 2 wherein said agent is released into a liquid environment in which said agent exhibits a finite solubility and in which said film and said core polymers are insoluble.
9. The device of claim 8 wherein said agent is present at a level of from 0.1 to 75 weight % of said core sheet.
- 15 10. The device of claim 8 wherein said core sheet contains a dispersed porosigen of finite solubility in said environment.
11. The device of claim 8 wherein said agent is characterized by finite solubility in an aqueous environment.
- 20 12. The device of claim 11 for oral administration to a ruminant, wherein said films and said core sheet are flexible and resilient and capable of constraintment in rolled configuration by constraining means releasable in an aqueous environment.
- 25 13. The device of claim 12 wherein said agent is an anthelmintic agent.
14. The device of claim 13 wherein said agent is a water-soluble acid addition salt of morantel, pyrantel and levamisole.
- 30 15. The device according to claim 14 wherein the core sheet and coextensive polymeric films comprise ethylene vinyl acetate copolymer.
16. The device of claim 15 wherein the perimeter edge of said core sheet is sealed by a film of ethylene vinyl acetate copolymer.
- 35 17. A three-layer laminate device for the controlled and continuous release of a water-soluble active agent to an aqueous liquid-containing environment over a prolonged period of time, said device comprising
 - 40 (a) a core sheet comprising a water soluble active agent dispersed in an amount corresponding to from 10% to 75% by weight of said core sheet, said sheet comprising a polymeric material insoluble in said aqueous liquid-containing environment, resilient, flexible and impermeable to said agent and to said environment, and which has been subjected to tensile stress below the yield point;
 - (b) said core sheet being sandwiched between two coextensive films of polymeric material which are resilient, insoluble in said aqueous liquid-containing environment, flexible and impermeable to said environment and to said agent;
 - 45 (c) the thus-produced three-layer laminate having one or a plurality of macroperforations extending through said films and said core;
 - (d) and being capable of constraintment by constraining means in a rolled-up configuration, the constraining means being operable to release the constrained laminate when said laminate is placed
 - 50 in an aqueous liquid-containing environment.
18. A device according to claim 17 wherein the aqueous liquid-containing environment is the rumenoreticular sac of a ruminant and the active agent is a water-soluble acid addition salt of morantel, pyrantel or levamisole.
- 55 19. A device according to claim 14, 15 or 18 wherein said agent is morantel citrate or tartrate.
20. A method of altering the inherent release rate of an active agent-containing polymeric matrix which

comprises subjecting said matrix to tensile stress below the yield point.

21. A method according to claim 20 wherein the stress is applied at levels at which 95% to 100% of the imposed strain is recoverable.
22. A process for making an active agent-containing polymer matrix device for controlled release of said agent to an ambient environment which comprises subjecting said device to tensile stress which does not exceed the yield point of the polymer.
23. A process according to claim 22 wherein the stress is applied at a constant rate.
24. A process according to claim 23 wherein the stress is applied in only one direction.
25. A process according to claim 22 wherein the device comprises an ethylene vinyl acetate copolymer matrix.
26. A process according to claim 23 wherein the device comprises an active agent-containing polymer matrix present as a core sheet sandwiched between coextensive polymeric films.
27. A process according to claim 26 wherein the core sheet is subjected to stress prior to being sandwiched between the coextensive polymeric films.
28. A process according to claim 23 wherein the active agent is an anthelmintic agent.
29. The process according to claim 28 wherein the anthelmintic agent is a water soluble acid addition salt of morantel.
30. The process according to claim 29 wherein the agent is morantel citrate or morantel tartrate.

Patentansprüche

1. Matrix-Vorrichtung zur kontrollierten Freisetzung eines aktiven Mittels in die Umgebung, umfassend eine ein aktives Mittel enthaltende Polymermatrix, wobei das Polymer einer Zugspannung unterhalb der Streckgrenze ausgesetzt wurde.
2. Vorrichtung nach Anspruch 1, worin die das aktive Mittel enthaltende Polymer-Matrix als Kernfolie vorhanden ist, die sich sandwichartig zwischen zwei Polymerfilmen gleicher Ausdehnung erstreckt, die für die Umgebung und das Mittel undurchlässig sind; wobei die Vorrichtung mindestens eine Makroperforation aufweist, die sich durch die Polymerfilme gleicher Ausdehnung und die Kernfolie erstreckt.
3. Vorrichtung nach Anspruch 2, worin die Makroperforationen über die Oberfläche der Vorrichtung symmetrisch verteilt sind und die Kernfolie eine homogene Mischung des aktiven Mittels in der Polymermatrix umfaßt.
4. Vorrichtung nach Anspruch 3, worin die Makroperforationen rund sind, um innere Kanten mit zylindrischer Konfiguration zu liefern für den Kontakt des Mittels mit der Umgebung.
5. Vorrichtung nach Anspruch 4, worin die Makroperforationen einen Durchmesser von 0,5 bis 10 mm haben.
6. Vorrichtung nach Anspruch 2, worin die Umfangskante der Kernfolie mit einem Film beschichtet ist, der für die Umgebung und das Mittel undurchlässig ist.
7. Vorrichtung nach Anspruch 2, worin das Mittel in der Kernfolie dispergiert ist.
8. Vorrichtung nach Anspruch 2, worin das Mittel in eine flüssige Umgebung abgegeben wird, worin das Mittel eine begrenzte Löslichkeit hat und worin Film- und Kernpolymere unlöslich sind.

9. Vorrichtung nach Anspruch 8, worin das Mittel in einem Anteil von 0,1 bis 75 Gew.-% der Kernfolie vorhanden ist.
10. Vorrichtung nach Anspruch 8, worin die Kernfolie ein dispergiertes Porosigen mit begrenzter Löslichkeit in der Umgebung enthält.
11. Vorrichtung nach Anspruch 8, worin das Mittel durch eine begrenzte Löslichkeit in einer wäßrigen Umgebung gekennzeichnet ist.
12. Vorrichtung nach Anspruch 11 zur oralen Verabreichung an Wiederkäuer, worin Filme und Kernfolie flexibel und rückstellbar sind und in einer aufgerollten Konfiguration festgehalten werden können, durch Zwangsmittel, die in einer wäßrigen Umgebung freisetzbare sind.
13. Vorrichtung nach Anspruch 12, worin das Mittel ein Anthelmintikum ist.
14. Vorrichtung nach Anspruch 13, worin das Mittel ein wasserlösliches Säure-Additionssalz von Morantel, Pyrantel und Levamisol ist.
15. Vorrichtung nach Anspruch 14, worin die Kernfolie und die Polymerfilme gleicher Ausdehnung Ethylvinylacetat-Copolymer enthalten.
16. Vorrichtung nach Anspruch 15, worin die Umfangskante der Kernfolie mit einem Film aus Ethylvinylacetat-Copolymer abgedichtet ist.
17. Dreischichtige Laminat-Vorrichtung für die kontrollierte und kontinuierliche Freisetzung eines wasserlöslichen aktiven Mittels in eine wäßrige Flüssigkeit enthaltende Umgebung über einen verlängerten Zeitraum, wobei die Vorrichtung umfaßt
 - (a) eine Kernfolie, die ein wasserlösliches aktives Mittel dispergiert enthält in einer Menge, die 10 bis 75 Gew.-% der Kernfolie entspricht, wobei die Folie ein Polymermaterial umfaßt, das in der wäßrigen Flüssigkeit enthaltenden Umgebung unlöslich ist, rückstellbar, flexibel und undurchlässig für das Mittel und die Umgebung ist und einer Zugspannung unterhalb der Streckgrenze ausgesetzt wurde;
 - (b) wobei die Kernfolie sandwichartig zwischen zwei Filmen mit gleicher Ausdehnung aus Polymermaterial angeordnet ist, die rückstellbar, unlöslich in der wäßrigen Flüssigkeit enthaltenden Umgebung, flexibel und undurchlässig für die Umgebung und das Mittel sind;
 - (c) wobei das so hergestellte dreischichtige Laminat eine oder eine Vielzahl von Makroperforationen aufweist, die sich durch die Filme und den Kern erstrecken;
 - (d) und die durch Zwangsmittel in einer aufgerollten Konfiguration festgehalten werden kann, wobei die Zwangsmittel eine Freisetzung des festgehaltenen Laminats bewirken können, wenn das Laminat in eine wäßrige Flüssigkeit enthaltende Umgebung gebracht wird.
18. Vorrichtung nach Anspruch 17, worin die wäßrige Flüssigkeit enthaltende Umgebung der Pansen-Netzmagen-Sack eines Wiederkäuers ist und das aktive Mittel ein wasserlösliches Säure-Additionssalz von Morantel, Pyrantel oder Levamisol ist.
19. Vorrichtung nach Anspruch 14, 15 oder 18, worin das Mittel Morantelcitrat oder Moranteltartrat ist.
20. Verfahren zur Veränderung der inhärenten Freisetzungsrates einer ein aktives Mittel enthaltenden Polymer-Matrix, das umfaßt, daß man die Matrix einer Zugspannung unterhalb der Streckgrenze aussetzt.
21. Verfahren nach Anspruch 20, worin die Spannung in einem Maß angewendet wird, daß 95 bis 100 % der angelegten Dehnung zurückfedern können.
22. Verfahren zur Herstellung einer ein aktives Mittel enthaltenden Polymer-Matrix-Vorrichtung zur kontrollierten Freisetzung des Mittels in eine Umgebung umfassend, daß man die Vorrichtung einer Zugspannung aussetzt, die die Streckgrenze des Polymers nicht übersteigt.

23. Verfahren nach Anspruch 22, worin die Spannung mit einer konstanten Rate angelegt wird.
24. Verfahren nach Anspruch 23, worin die Spannung nur in einer Richtung angelegt wird.
- 5 25. Verfahren nach Anspruch 22, worin die Vorrichtung eine Ethylenvinylacetat-Copolymer-Matrix umfaßt.
26. Verfahren nach Anspruch 23, worin die Vorrichtung eine ein aktives Mittel enthaltende Polymer-Matrix umfaßt, die als Kernfolie vorhanden ist, sandwichartig zwischen Polymerfilmen gleicher Ausdehnung angeordnet.
- 10 27. Verfahren nach Anspruch 26, worin die Kernfolie einer Spannung ausgesetzt wird, bevor sie sandwichartig zwischen den Polymerfilmen gleicher Ausdehnung angeordnet wird.
28. Verfahren nach Anspruch 23, worin das aktive Mittel ein Anthelmintikum ist.
- 15 29. Verfahren nach Anspruch 28, worin das Anthelmintikum ein wasserlösliches Säure-Additionssalz von Morantel ist.
30. Verfahren nach Anspruch 29, worin das Mittel Morantelcitrat oder Moranteltartrat ist.

Revendications

1. Dispositif à matrice pour la libération contrôlée d'un agent actif dans un milieu ambiant, comprenant une matrice de polymère contenant un agent actif, polymère qui a été soumis à une contrainte de traction inférieure au point de fluage.
- 25 2. Dispositif suivant la revendication 1, dans lequel la matrice de polymère contenant un agent actif est présente sous forme d'une feuille centrale intercalée entre des films polymériques co-extensifs qui sont imperméables vis-à-vis du milieu ambiant et dudit agent ; ledit dispositif comprenant au moins une macroperforation s'étendant à travers lesdits films polymériques co-extensifs et ladite feuille centrale.
- 30 3. Dispositif suivant la revendication 2, dans lequel les macroperforations sont distribuées de manière symétrique sur la face dudit dispositif et ladite feuille centrale comprend un mélange homogène d'agent actif dans la matrice de polymère.
- 35 4. Dispositif suivant la revendication 3, dans lequel les macroperforations sont circulaires pour former des bords intérieurs de configuration cylindrique pour la mise en contact de l'agent avec le milieu ambiant.
- 40 5. Dispositif suivant la revendication 4, dans lequel les macroperforations ont un diamètre de 1,5 à 10 mm.
6. Dispositif suivant la revendication 2, dans lequel le bord périphérique de la feuille centrale est revêtu d'un film imperméable vis-à-vis du milieu ambiant et de l'agent.
- 45 7. Dispositif suivant la revendication 2, dans lequel l'agent est dispersé dans la feuille centrale.
8. Dispositif suivant la revendication 2, dans lequel l'agent est libéré dans un milieu liquide dans lequel ledit agent présente une solubilité finie et dans lequel les polymères des films et de la feuille centrale sont insolubles.
- 50 9. Dispositif suivant la revendication 8, dans lequel l'agent est présent en une teneur de 0,1 à 75 % en poids de la feuille centrale.
10. Dispositif suivant la revendication 8, dans lequel la feuille centrale contient un agent dispersé engendrant des pores, de solubilité finie dans le milieu ambiant.
- 55 11. Dispositif suivant la revendication 8, dans lequel l'agent est caractérisé par une solubilité finie dans un milieu aqueux.

12. Dispositif suivant la revendication 11 pour l'administration orale à un ruminant, dans lequel les films et la feuille centrale sont flexibles et résilients et capables d'être maintenus sous contrainte sous la configuration enroulée par des moyens de contrainte libérables dans un milieu aqueux.
- 5 13. Dispositif suivant la revendication 12, dans lequel l'agent est un agent anthelminthique.
14. Dispositif suivant la revendication 13, dans lequel l'agent est un sel d'addition d'acide hydrosoluble de morantel, de pyrantel ou de levamisole.
- 10 15. Dispositif suivant la revendication 14, dans lequel la feuille centrale et les films polymériques coextensifs comprennent un copolymère éthylène-acétate de vinyle.
16. Dispositif suivant la revendication 15, dans lequel le bord périphérique de la feuille centrale est recouvert de manière étanche par un film de copolymère éthylène-acétate de vinyle.
- 15 17. Dispositif stratifié à trois couches pour la libération contrôlée et continue d'un agent actif hydrosoluble dans un milieu contenant un liquide aqueux pendant un temps prolongé, ledit dispositif comprenant
 - (a) une feuille centrale comprenant un agent actif hydrosoluble dispersé en une quantité correspondant à une valeur de 10 % à 75 % en poids de ladite feuille centrale, ladite feuille comprenant une
 - 20 matière polymérique insoluble dans ledit milieu contenant un liquide aqueux, résiliente, flexible et imperméable audit agent et audit milieu ambiant, et qui a été soumise à une contrainte de traction inférieure au point de fluage ;
 - (b) ladite feuille centrale étant intercalée entre deux films co-extensifs de matière polymérique qui sont résilients, insolubles dans ledit milieu contenant un liquide aqueux, flexibles et imperméables
 - 25 vis-à-vis dudit milieu ambiant et dudit agent ;
 - (c) le stratifié en trois couches ainsi produit comprenant une ou plusieurs macroporations s'étendant à travers lesdits films et ladite feuille centrale ;
 - (d) et étant capable d'être maintenu sous contrainte par des moyens de contrainte sous une configuration enroulée, les moyens de contrainte pouvant fonctionner de manière à libérer le stratifié
 - 30 sous contrainte lorsque ledit stratifié est placé dans un milieu contenant un liquide aqueux.
18. Dispositif suivant la revendication 17, dans lequel le milieu contenant un liquide aqueux est le sac ruménoréticulaire d'un ruminant et l'agent actif est un sel d'addition d'acide hydrosoluble de morantel, de pyrantel ou de levamisole.
- 35 19. Dispositif suivant la revendication 14, 15 ou 18, dans lequel l'agent est le citrate ou tartrate de morantel.
20. Procédé pour modifier la vitesse de libération inhérente d'une matrice polymérique contenant un agent actif, qui consiste à soumettre ladite matrice à une contrainte de traction inférieure au point de fluage.
- 40 21. Procédé suivant la revendication 20, dans lequel la contrainte est appliquée à des valeurs auxquelles 95 % à 100 % de la déformation imposée sont aptes à une reprise dimensionnelle.
22. Procédé de production d'un dispositif à matrice polymérique contenant un agent actif pour la libération contrôlée dudit agent dans un milieu ambiant, qui consiste à soumettre ledit dispositif à une contrainte de traction qui n'excède pas le point de fluage du polymère.
- 45 23. Procédé suivant la revendication 22, dans lequel la contrainte est appliquée à vitesse constante.
- 50 24. Procédé suivant la revendication 23, dans lequel la contrainte est appliquée dans une seule direction.
25. Procédé suivant la revendication 22, dans lequel le dispositif comprend une matrice de copolymère éthylène-acétate de vinyle.
- 55 26. Procédé suivant la revendication 23, dans lequel le dispositif comprend une matrice polymérique contenant un agent actif présente comme feuille centrale intercalée entre des films polymériques co-extensifs.

EP 0 266 929 B1

27. Procédé suivant la revendication 26, dans lequel la feuille centrale est soumise à une contrainte avant d'être intercalée entre les films polymériques co-extensifs.
- 5 28. Procédé suivant la revendication 23, dans lequel l'agent actif est un agent anthelminthique.
29. Procédé suivant la revendication 28, dans lequel l'agent anthelminthique est un sel d'addition d'acide hydrosoluble de morantel.
- 10 30. Procédé suivant la revendication 29, dans lequel l'agent est le citrate de morantel ou le tartrate de morantel.
